

treatment should be assessed by taking into consideration the demonstrable objective changes that are observed by physical examination and appropriate radiologic studies (CT, MRI, and PET). Tumor measurements by MRI and CT shall be recorded at least every 8 weeks during the first 2 years of treatment. Once an objective response is accomplished, it is recommended that treatment be continued until complete remission occurs and for 8 months thereafter. It is recommended that the patient have laboratory tests, including hematology and chemistry studies, performed weekly during the first 6 weeks and at least every 3 weeks thereafter during the course of treatment. Patients receiving A10 at a dosage of 5.5 g/kg/day should have their serum electrolytes checked at least once weekly. Patients receiving A10 at dosages in excess of 5.5 g/kg/d should have their serum electrolytes checked at least three times weekly (for example, Monday, Wednesday, and Friday) or more frequently as medically indicated. Testing for serum levels of sodium, potassium, chloride, and bicarbonate should always be included; testing for serum levels of magnesium, calcium, and phosphorus should be included in at least half of those determinations. During antineoplaston dose escalation, all patients should have these electrolyte determinations performed at least every other day. Patients who have been on antineoplastons injections for more than 60 days may have electrolyte levels determined twice per week, provided that they have been on a stable dosage for at least 2 weeks, have a normal serum sodium, and do not have any other serum electrolyte abnormalities.

---

## Credentialing

There are no license requirements for this type of therapy. A10 and AS2-1 are available throughout the entire United States in Phase II studies that are supervised by the FDA. Administration of antineoplaston agents must be performed under the supervision of a physician.

---

## Training

No special training is required.
